

Pulmonary Embolus

This leaflet offers more information about pulmonary embolus. If you have any further questions or concerns, please speak to the staff member in charge of your care.

What is a pulmonary embolus and why have I got it?

A pulmonary embolus (PE) is a blockage of one or more of the blood vessels in the lungs.

It is commonly caused by a blood clot that has developed in the leg or pelvic veins, which then breaks off and travels to the lungs.

Sometimes PEs happen for no obvious reason.

Sometimes they may happen as a result of the following:

- surgery
- trauma such as fractures or muscle injuries
- long periods of inactivity for example being in bed with 'flu
- long journeys including flights of over four hours duration or long unbroken car journeys
- pregnancy and childbirth
- certain types of oral contraceptive pill or hormone replacement therapy
- obesity
- cancer
- a previous DVT (deep vein thrombosis).

Some people have an inherited or acquired tendency for their blood to clot. This is called thrombophilia and can mean a PE is more likely to happen. It can affect other members of the family and you will be given advice about this if needed.

What are the signs and symptoms?

The signs and symptoms of PE are:

- shortness of breath
- chest pain
- coughing up blood
- collapse in severe cases.

Do I need any tests to confirm the diagnosis?

If you show symptoms of a PE you may have one or more of the following tests:

- **chest X-ray** – to help diagnose a PE but mainly to check there is no other cause.
- **VQ scan** – a two-part scan to confirm diagnosis of PE. Firstly, a contrast dye is injected into the lungs so the scanner can see the blood flow. Secondly, you are asked to breathe in a harmless gas that will show the air flow in the lungs. The two parts are then matched and looked at by a radiologist to see if you have a PE.
- **CTPA** – a non-invasive scan to try to see if you have a blood clot if other tests are not clear.
- **pulmonary angiogram** – a non-routine test where a dye is injected into the blood vessels in the lung, so any blockages will show on an X-ray.
- **electrocardiogram (ECG)** – a test to trace your heart rhythm to help confirm if you have a PE.

- **echocardiogram** – a non-invasive ultrasound test to show any effects of PE on the heart.
- **blood gas analysis** – a blood test to see how much oxygen is in your blood, as there may be less than normal after a PE.
- **ultrasound** – a painless test where an ultrasound probe is used to look for clots in the deep veins of your legs or pelvis. If a clot is detected this may help confirm a PE diagnosis.

What treatments are available?

Once PE is confirmed you will be started on **anticoagulant** drugs which make your blood take longer to clot (sometimes called thinning the blood or making it less sticky). This happens straightaway and lessens the risk of your clot getting any bigger. Your body can then dissolve the clot itself over the next few weeks.

The most commonly used anticoagulants are called rivaroxaban, heparin and warfarin.

You will be started on rivaroxaban, unless you cannot have this for any reason in which case you will be started on heparin or warfarin.

- **Rivaroxaban** – you will need to take one 15mg tablet twice a day for three weeks, followed by one tablet once a day (usually 20mg). The tablets must be taken with food.
- **Heparin** – is usually given by injection under the skin once a day or by a drip into a vein. Warfarin tablets are also started and heparin is stopped when the warfarin starts to work fully.
- **Warfarin** – is taken once a day in tablet form. It takes several days to have a full effect so is used with heparin until the right blood level is reached, when the heparin is stopped.

Clot buster (thrombolytic) drugs may be used to dissolve the blood clot if the PE is life threatening. Anticoagulants are still needed after this. This is not a common treatment.

Surgery to remove the clot is only needed in a small number of patients if the PE is life threatening. Anticoagulants are still needed after this.

IVC filter is used very rarely, when anticoagulants on their own may not stop a PE happening again. A filter is put into the main blood vessel carrying blood to the heart (the inferior vena cava) to trap clots and stop them reaching your lungs. It is usually removed 10 to 12 days later when the risk is lower, although it may be left in place permanently.

What happens next?

Your anticoagulant treatment will need to be reviewed at the **anticoagulant clinic**.

If you are taking warfarin the clotting time of your blood must be regularly checked and measured against a standard. This gives us your International Normalised Ratio (INR), which we will normally try to keep between two and three, meaning your blood will take two to three times longer to clot than normal. Your dose of warfarin may be changed according to your INR.

As warfarin can affect other medications you must tell anyone prescribing other drugs for you that you are on warfarin.

Please also tell the anticoagulant clinic straight away if there are any changes to your other drugs.

Most people take anticoagulants for a minimum of three months.

You may need to have treatment for longer depending on the cause of the blood clot and how bad it is.

If you have had a clot before then you may be advised to stay on warfarin for life.

After stopping warfarin you may be asked to have a blood test to check whether you have an inherited or acquired tendency to develop blood clots.

What do I need to do after I go home?

You should not return to work until your acute symptoms have gone, usually after six weeks. Your GP can advise about returning to work.

You may continue to have chest pain for several weeks after your PE. Take regular painkillers to help this and if your chest pain changes or gets worse seek medical advice straightaway (see below).

You should only start driving again when you can carry out an emergency stop without feeling too much pain.

Being overweight can increase the risk of a clot developing so try to lose weight if needed.

There is no medical reason to refrain from sex after a blood clot.

Your doctor will tell you if there is anything else you should do or not do. This may depend on how bad your PE is.

What should I do if I have a problem?

If you experience any of the following contact your GP straight away:

- worse shortness of breath
- new or worse chest pain
- coughing up blood.

Will I get another blood clot?

The risk of this depends on what caused your clot.

You should take special precautions during:

- airline flights, particularly if longer than four hours
- long periods of inactivity
- pregnancy.

You will also need to take extra precautions and advice after surgery, trauma or lower limb fracture.

You should check with your GP first if you are thinking of taking hormone replacement therapy or the combined oral contraceptive pill.

If you are admitted to hospital you must tell your doctor that you have had a blood clot.

Contact us

If you have any questions or concerns about pulmonary embolus, please contact the anticoagulant clinic on 020 8725 1332 (Monday to Friday, 9am to 5pm). Out of hours, please contact our switchboard on 020 8672 1255 and ask for the haematology specialist registrar on call.

For more information leaflets on conditions, procedures, treatments and services offered at our hospitals, please visit www.stgeorges.nhs.uk

Additional services

Patient Advice and Liaison Service (PALS)

PALS can offer you on-the-spot advice and information when you have comments or concerns about our services or the care you have received. You can visit the PALS office between 9.30am and 4.30pm, Monday to Friday in the main corridor between Grosvenor and Lanesborough Wing (near the lift foyer).

Tel: 020 8725 2453 **Email:** pals@stgeorges.nhs.uk

NHS Choices

NHS Choices provides online information and guidance on all aspects of health and healthcare, to help you make decisions about your health.

Web: www.nhs.uk

NHS 111

You can call 111 when you need medical help fast but it's not a 999 emergency. NHS 111 is available 24 hours a day, 365 days a year. Calls are free from landlines and mobile phones.
